Interleukins 33 and 1B serum levels and common carotid arteries remodeling in hypertensive patients with obesity

Oleksii Honchar, Olga Kovalyova
Kharkiv National Medical University, Propedeutics To Internal Medicine
No.1, Kharkiv, Ukraine

Objective: To investigate interrelations between interleukin 33 (IL-33) and 1 β (IL-1 β) serum levels and common carotid arteries (CCA) remodeling in hypertensive patients with obesity.

Method: 80 hypertensive patients (51 obese) have been observed. An ultrasound examination of CCA with estimation of its geometrical type was performed (cut-off value for vascular wall hypertrophy was vascular segment mass >0,275 g/cm, concentric remodeling was diagnosed with relative wall thickness of CCA >0,2). IL-33 and IL-1B serum levels were estimated using ELISA.

Results: IL-33 and IL-1 β levels were higher in hypertensive patients ($p < 0,001$), independently of BMI. Cluster analysis was made to reveal both cytokines' levels impact on CCA geometry (see picture). IL-33 ≥ 73 pg/ml, IL-1 $\beta \geq 25$ pg/ml was associated with 80,0% prevalence of normal CCA geometry and 20,0% of its concentric hypertrophy. IL-1 $\beta \geq 20$ pg/ml with IL-33 < 71 pg/ml was characterized by 80,0% prevalence of normal geometry, 10,0% of non-hypertensive concentric remodeling of CCA, 5,0% of concentric and 5,0% of eccentric hypertrophy. IL-33 ≥ 71 pg/ml with IL-1 $\beta < 25$ pg/ml was associated with decrease of normal CCA geometry prevalence to 50,0% with increase of concentric hypertrophy rate to 41,7%; other 8,3% patients had eccentric hypertrophy of CCA. IL-33 < 71 pg/ml, IL-1 $\beta < 20$ pg/ml ($p > 0,05$ vs control group) had 57,9% of normal geometry, 15,8% of concentric remodeling, 15,8% of concentric hypertrophy and 10,5% of eccentric hypertrophy of CCA.

Conclusion: IL-33 and IL-1 β serum levels were elevated in hypertensive patients independently of presence of obesity. A pronounced isolated increase in IL-33 level was associated with abrupt increase of CCA hypertrophy prevalence, especially its concentric variant. Accompanying increase in IL-1B level reduced this effect.

Abdominal aortic aneurysms repair by entirely percutaneous endovascular approach using closure suture-based device. Prospective study of safety, feasibility and efficiency

Redouane Saady (1), Antoine Sauguet (2), Denis Doyen (1), Emile Ferrari (1), Jean Fajadet (2)
(1) CHU Nice, Cardiologie, Nice, France – (2) Clinique Pasteur, Cardiologie, Toulouse, France

Background: Endovascular repair of abdominal aortic aneurysms (AAA) is a well documented option. This approach is usually performed by surgical cut down of the common femoral arteries (CFA). Total percutaneous access for endovascular aortic aneurysm repair (« preclose technique ») has been reported. However high bleeding risk obese patients are still considered as bad candidates for this method.

Aims: We describe our experience of the entirely percutaneous vascular approach using the Prostar XL system, in our obese population in particular.

Methods: We analyzed 164 consecutive patients treated for AAA by endovascular percutaneous route between January 2007 and February 2012. Mean age of our patients was 76 years old. 25.8% of our population were obese (mean body mass index = 36). All patients were treated with a bifurcated endoprosthesis. The diameter of the introducer was 18-French (F) for the main femoral access and 12F for the controlateral access. The success rate of the procedure has been described elsewhere. A total of non-surgical 328 femoral access sites were closed with the Prostar XL system.

Results: The success rate of the entirely percutaneous vascular approach procedure was 94,5% and reached 100% in obese population, with a mean delay to hospital discharge of 6 days. Nine procedure failures were deployed. All procedure failures occurred on the 18F side while the success rate was 100% with 12F introducers ($p = 0,002$). Re-hospitalization rate due to vascular access complication (haematoma, false aneurysm, femoral abscess) was 2.4%

after a mean follow-up of 23 months, but no difference between obese and non-obese patients was found.

Conclusion: Our results indicate that even in obese patients, usually considered as relatively contra-indicated to this strategy, the entirely percutaneous approach using the Prostar device for endovascular treatment of infrarenal AAA is safe.

Analysis of blood pressure variability in the systolic hypertension with telemonitoring: feasibility and results on 108 patients

Patrick Dary
Cabinet de Cardiologie, Saint Yrieix La Perche, France

Purpose: Blood pressure (BP) and its variability (BPV) are associated with an increased risk for cardiovascular mortality. This observational study explores the benefits of patients telemonitoring using self-measured BP to optimise treatment and its usefulness in the variability analysis

Methods: Patients with uncontrolled hypertension were enrolled during an appointment. 2 SMBP were taken in the morning, at midday and in the evening at set times, the results being sent to a secure server. After 5 days treatment was started if the mean reading was more than 140/90. Variability analysis has been realized during all the follow up. The evaluation made at the end of the first 5 days to obtain the mean, standart Deviation (SD), coefficient of variation (CV), hight and low BP

Results: 63 women and 45 men. BP = 176/96 at inclusion dropping to 160/88 after 5 days under the same treatment. Therapeutic adjustments achieved over 12.7 days with significant decrease in BP to 143/82: -17 systolic and -6 diastolic ($p < 0,0001$)

Results of variability are SD=16.63 \pm 5 and CV=0.105 \pm 0.03. There is no difference according age (<70 years CV 0.104/>70 years CV 0.106, $p = 0,582$) or the level of BP (BP < 160 mmhg CV 0.109/ BP > 160mm hg CV 0.100; $p = 0,100$). At first variability is of 0.105 (32 measures, 4.7 days) with a not significant increase at the end: 0.112 (52 measures; $p = 0,098$)

When variability >0.10, the risk of low BP increases (104/118, $p < 0,0001$; CV = 0.136/0.087, $p < 0,0001$), for the same mean BP(146/142, $p = 0,152$), number of treatment (2.71/2.86, $p = 0,443$) and for the same age (69,8/66,8, $p = 0,152$) SBP of all measures is lowest at midday: 164mm hg morning, 153mm hg midday (-11mm, $p < 0,0001$), 163mm hg evening with the same difference at the end of follow up (147/138). The gap increases >74 years (-14mm de hg; 170/156)

Conclusions: Awareness of the variance between average clinic and average telemonitoring BP may influence the diagnostic and management of hypertension. Telemonitoring of BP allows the real time measure of the mean, SD, CV and hight and low BP after modification or new treatment. The real time analysis allows the control of hypertension to improve (figure next page).

Plasma interleukin-18 levels depend on hypertriglyceridemic waist phenotype and gender in patients with arterial hypertension

Tetyana Ashcheulova, Ime Ime Etukudo, Olga Kovalyova, Abdel Nur Abdel Nur
Kharkiv National Medical University, Internal Medicine, Kharkiv, Ukraine

The aim our study was to investigate cardiometabolic risk factors and plasma interleukin-18 (IL-18) levels in relationships with hypertriglyceridemic waist phenotype (HTGW) depend on gender of patients with arterial hypertension (AH).

Methods: Anthropometric parameters, carbohydrate and lipid metabolism, circulating IL-18 levels in 101 patients with AH (men (n=45; 44.6%) and women (n=56; 55.4 %) aged 32-80 years) were examined. HTGW was defined

20 To 26/3	Mean BPS	Mean BPD	MAX BPS	MIN BPS	CV	Number BP	BPS>16
	157	98	181	130	0.09	24	50%

27 to 11/4	Mean BPS	Mean BPD	MAX TAS	MIN TAS	CV	Number BP	BPS>16
	150	96	174	103	0.10	60	27%

Abstract 0032 – Figure: Variability analysis

as a waist circumference (WC) of 90cm and more in male, and 85cm and more in female, and a triglyceride level of 1.7 mmol/L or more. Patients were categorized into 3 phenotype groups: 1st with hypertriglyceridemia and normal WC, 2nd with normal triglyceride level and increased WC, 3rd with HTGW.

Results: The patients of 3rd group characterized by maximum blood pressure levels. Body mass index (BMI) in 3rd group was also highest ($31.05 \pm 0.61 \text{ kg/m}^2$) vs 1st ($23.95 \pm 0.91 \text{ kg/m}^2$) and 2nd one ($30.21 \pm 1.00 \text{ kg/m}^2$). Fasting insulin levels were elevated in patients of 3rd group with HTGW ($14.66 \pm 0.95 \text{ mkU/ml}$), and same in 1st ($12.52 \pm 2.79 \text{ mkU/ml}$) and 2nd ($12.31 \pm 1.41 \text{ mkU/ml}$) groups.

IL-18 – pro-inflammatory cytokine levels in 3rd group were $176.97 \pm 2.38 \text{ pg/ml}$, that was statistically higher in comparison with 1st ($167.73 \pm 7.21 \text{ pg/ml}$), and 2nd group ($172.40 \pm 5.61 \text{ pg/ml}$; $p < 0.05$). Plasma IL-18 in 2nd group was higher in men ($172.40 \pm 5.61 \text{ pg/mg}$) vs women ($169.53 \pm 7.04 \text{ pg/ml}$; $p < 0.05$); whereas in 1st group women characterized by significantly higher IL-18 content ($169.00 \pm 1.11 \text{ pg/ml}$) compared with men ($160.83 \pm 9.35 \text{ pg/ml}$; $p < 0.05$). The same tendency was found in group 3 with HTGW phenotype presence where IL-18 content in women ($180.62 \pm 2.93 \text{ pg/ml}$) exceed cytokine level in men ($167.76 \pm 3.52 \text{ pg/ml}$; $p < 0.05$).

Conclusions: Our results can suggest that HTGW phenotype is associated with more significant in women elevation of pro-inflammatory activity, high glucometabolic risk and atherogenic metabolic risk profile and can be used as a simple and inexpensive marker to help identify patients with high cardiometabolic risk.

0151

The peculiarities of pulse pressure variation and renal function in patients with arterial hypertension

Larysa Zhuravlyova, Iryna Ilcenko, Maryna Filonenko
Kharkiv National medical university, Internal medicine N3, Kharkiv, Ukraine

The purpose of the study was to establish the relationship between the pulse pressure (PP) changes and renal function in patients with arterial hypertension (AH).

Methods: 47 patients with AH of 2nd stage without diabetes and obesity were examined (25 males and 22 females, mean age – 52.5 ± 4.3 years, duration of AH – 8.7 ± 3.5 years; BMI $24.3 \pm 3.7 \text{ kg/m}^2$). The indexes of lipid blood profile, glycemia, and blood creatinine were assessed, as well as glomerular filtration rate (GFR, ml/min/m^2) according to MDRD (Modification of Diet in Renal Disease Study) and standardized for body surface area – 1.73 m^2 ; also ambulatory blood pressure monitoring was performed.

Results: The indexes of daily mean systolic (SBP) and daily mean diastolic (DBP) blood pressure were: $159.4 \pm 8.3 \text{ mm Hg}$ and $96.8 \pm 5.4 \text{ mm Hg}$ respectively. The changing of the circadian rhythm was observed in 94% of patients, of which 73% had “non-dipper” type; 19% – “night-peaker”, 8% – “dipper”. A direct correlation was established between the level of PP and SBP ($\tau = 0.788$; $p < 0.001$); PP and DBP ($\tau = 0.316$; $p < 0.005$). The increase of PP depended on the augmentation of SBP to the greater extent than of DBP. A direct correlation between PP and blood creatinine levels was found ($\tau = 0.36$; $p < 0.001$), as well as the inverse correlation between PP and GFR ($\tau = -0.284$; $p < 0.005$), which confirms the relationship between increasing levels of PP and decrease of the filtration capacity of the kidneys.

Conclusions: In patients with hypertension the increase of PP depends on the augmentation of SBP to the greater extent than of DBP. The relationship between the increase of PP and decreased functional capacity of the kidneys is confirmed. The management of antihypertensive therapy based on the dynamics of PP may prevent the development and progression of severe renal disease and renal failure.

Pulmonary embolism in Behçet's disease: a series of 10 patients

Tounsi Ahmed (1), Abid Leila (1), Abid Dorra (1), Triki Feten (1), Elaoud Sahar (2), Frikha Feten (2), Hentati Mourad (1), Bahloul Zouhir (2), Kam-moun Samir (1)
(1) CHU Hédi Chaker, Cardiologie, Sfax, Tunisie – (2) CHU Hédi Chaker, Médecine interne, Sfax, Tunisie

Background and objective: Pulmonary embolism is an unusual complication of Behçet's disease (BD). Our aim study is to analyse epidemiological, physiopathological and evolutive aspects of this condition.
